Here have been economic black fly or parasite infestation measurements to assess the project to date. They indicate little resettlement of the lands in the heavily infected areas because of other factors. Black fly (infected) pop. is effectively reduced by spraying but new infestation from areas beyond the control zones introduce reinfestation over distances previously thought impossible. It seems to be a "disease suppression program" not eradication. It is expensive and only affects one of many health problems in the countries. There is no end in sight. It is still considered the least expensive.
