mechanism of "DNA loss"

Obviously it is still hard to rule out selection. I don't have the growth data in front of me. However even if there were not net increase in total cell count, a turnover involving a balance of cell death and division cycles in 24 hours could also account for top minus from 5% to 20%.

Cell count can also be misleading: hypothetically large multinucleate cells could split into 2 or 4 tiny cells with no real growth, or 1 also balance the death of tol+.

I hope we can discuss this in more detail.
