

Prof J Lederberg

I attended the seminar on the sex ratio, and heard the lecturer from Oregon.

The variation he was able to correlate was with age of the father. You showed him how to correlate the anomalous fourth moment with familial choice.

He did not mention a hypothesis to correlate seasonal variation, nor number of birth. A number of reasonable explanations present themselves. Another problem is the variation with race. I believe a single hypothesis will explain all these variations; however I should first need to know that for horses, the correlation with number of birth is absent before I could put forth my p hypothesis with confidence. Is this information available?
